Back-of-the-envelope Estimation

In a system design interview, sometimes you are asked to estimate system capacity or performance requirements using a back-of-the-envelope estimation. According to Jeff Dean, Google Senior Fellow, "back-of-the-envelope calculations are estimates you create using a combination of thought experiments and common performance numbers to get a good feel for which designs will meet your requirements" [1].

You need to have a good sense of scalability basics to effectively carry out back-of-the-envelope estimation. The following concepts should be well understood: power of two [2], latency numbers every programmer should know, and availability numbers.

Although data volume can become enormous when dealing with distributed systems, calculation all boils down to

Power of two

the basics. To obtain correct calculations, it is critical to know the data volume unit using the power of 2. A byte is a sequence of 8 bits. An ASCII character uses one byte of memory (8 bits). Below is a table explaining the data volume unit (Table 1). Full name **Short name** Power Approximate value

10	1 Thousand	1 Kilobyte	1 KB	
20	1 Million	1 Megabyte	1 MB	
30	1 Billion	1 Gigabyte	1 GB	
40	1 Trillion	1 Terabyte	1 TB	
50	1 Quadrillion	1 Petabyte	1 PB	
Table 1				

Latency numbers every programmer should know

Dr. Dean from Google reveals the length of typical computer operations in 2010 [1]. Some numbers are outdated

as computers become faster and more powerful. However, those numbers should still be able to give us an idea of the fastness and slowness of different computer operations. **Operation name Time**

L1 cache reference	0.5 ns
Branch mispredict	5 ns
L2 cache reference	7 ns
Mutex lock/unlock	100 ns
Main memory reference	100 ns
Compress 1K bytes with Zippy	10,000 ns = 10 μs
Send 2K bytes over 1 Gbps network	20,000 ns = 20 μs
Read 1 MB sequentially from memory	250,000 ns = 250 μs
Round trip within the same datacenter	500,000 ns = 500 μs
Disk seek	10,000,000 ns = 10 ms
Read 1 MB sequentially from the network	10,000,000 ns = 10 ms
Read 1 MB sequentially from disk	30,000,000 ns = 30 ms
Send packet CA (California) ->Netherlands->CA	150,000,000 ns = 150 ms
Table 2	

ns = nanosecond, μs = microsecond, ms = millisecond

Notes

 $1 \mu s = 10^{-6} seconds = 1,000 ns$

Branch mispredict: 3ns

1 ms = 10^{-3} seconds = $1,000 \mu s = 1,000,000 ns$

 $1 \text{ ns} = 10^{-9} \text{ seconds}$

- consideration. Figures 2-1 shows the visualized latency numbers as of 2020 (source of figures: reference material [3]).
- Main memory reference: 100ns L1 cache reference: 1ns 1,000ns $\approx 1 \mu$ s

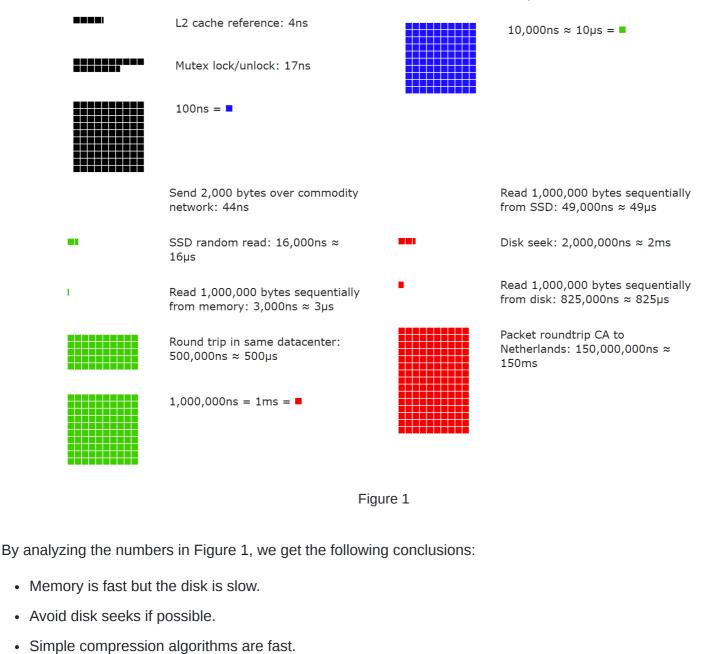

Compress 1KB wth Zippy: 2,000ns

52.60 minutes

5.26 minutes

31.56 seconds

A Google software engineer built a tool to visualize Dr. Dean's numbers. The tool also takes the time factor into

Data centers are usually in different regions, and it takes time to send data between them.

High availability is the ability of a system to be continuously operational for a desirably long period of time. High availability is measured as a percentage, with 100% means a service that has 0 downtime. Most services fall

Compress data before sending it over the internet if possible.

between 99% and 100%. A service level agreement (SLA) is a commonly used term for service providers. This is an agreement between you

8.64 seconds

86.40 milliseconds

864.00

to the expected system downtime.

99.99%

99.999%

99.9999%

Assumptions:

Estimations:

300 million monthly active users.

• Users post 2 tweets per day on average.

50% of users use Twitter daily.

10% of tweets contain media.

• Data is stored for 5 years.

Availability numbers

Availability % Downtime per day Downtime per week Downtime per month Downtime per year 99% 14.40 minutes 1.68 hours 7.31 hours 3.65 days

4.38 minutes

26.30 seconds

2.63 seconds

1.01 minutes

6.05 seconds

604.80

(the service provider) and your customer, and this agreement formally defines the level of uptime your service will deliver. Cloud providers Amazon [4], Google [5] and Microsoft [6] set their SLAs at 99.9% or above. Uptime is traditionally measured in nines. The more the nines, the better. As shown in Table 3, the number of nines correlate

Table 3 **Example: Estimate Twitter QPS and storage** requirements Please note the following numbers are for this exercise only as they are not real numbers from Twitter.

Query per second (QPS) estimate: Daily active users (DAU) = 300 million * 50% = 150 million Tweets QPS = 150 million * 2 tweets / 24 hour / 3600 seconds = ~3500

· text 140 bytes media 1 MB

Average tweet size:

tweet_id 64 bytes

• Peek QPS = 2 * QPS = ~7000

We will only estimate media storage here.

- 5-year media storage: 30 TB * 365 * 5 = ~55 PB **Tips**
- results. Interviewers may test your problem-solving skills. Here are a few tips to follow: · Rounding and Approximation. It is difficult to perform complicated math operations during the interview. For example, what is the result of "99987 / 9.1"? There is no need to spend valuable time to solve complicated
- math problems. Precision is not expected. Use round numbers and approximation to your advantage. The division question can be simplified as follows: "100,000 / 10". Write down your assumptions. It is a good idea to write down your assumptions to be referenced later.

Media storage: 150 million * 2 * 10% * 1 MB = 30 TB per day

Write down the units because "5 MB" helps to remove ambiguity. • Commonly asked back-of-the-envelope estimations: QPS, peak QPS, storage, cache, number of servers, etc. You can practice these calculations when preparing for an interview. Practice makes perfect.

• Label your units. When you write down "5", does it mean 5 KB or 5 MB? You might confuse yourself with this.

Back-of-the-envelope estimation is all about the process. Solving the problem is more important than obtaining

- Congratulations on getting this far! Now give yourself a pat on the back. Good job!
